

Switches & Cooperativity:

Lac Operon Monod & Jacob

E. coli: different energy sources. Likes glucose, then lactose. If no lactose then don't make the enzymes that process it

LacI - always on - in absence of lactose binds & represses the lac operon

Other factor: Low Glucose & Lactose → hi level

② Like an AND gate

Lo glucose AND lactose = ON(Hi)

hi glucose AND lactose = ON(Lo)

hi glucose NO Lactose = OFF

lo glucose NO Lactose = OFF

The Switch: there's +ve feed back

No feedback

$X \rightarrow Y$

+ve feed back

$X \rightarrow Y$

So

We will develop this on Wed :

Figure 1.1. A λ phage. The λ chromosome is 50,000 base pairs long and is wrapped around a core in the head.

its own gene. (How the repressor-encoding gene gets turned on in the first place immediately following infection when there is no repressor present—will be explained in Chapter 3.)

Although there is only one prophage in a lysogen there are about 10⁶ molecules of repressor, and the excess repressor is free to bind to any additional chromosome that might be injected into the cell. This has the result illustrated in Figure 1.3: λ cannot grow lytically on a λ -lysogen. The lysogen is said to be immune to infection.

Ultraviolet irradiation of lysogens inactivates repressor. As a result a second regulatory protein—Cro—is synthesized. Cro, which promotes and is required for growth, also binds DNA—in fact it binds to the same operator sites as does repressor but with opposite physiological effects. These two regulatory proteins, together with RNA polymerase and their promoter and operator sites on DNA, constitute the

Figure 1.2. Growth of phage λ . The injected λ chromosome may either lyse or lysogenize the host. Ultraviolet irradiation of a lysogen induces lytic growth. Induction of lysogens was first demonstrated for a prophage of the bacterium *Bacillus megaterium*.

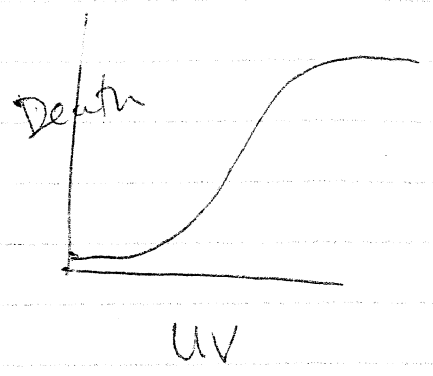

Figure 1.3. Immunity of a λ -lysogen. Lambda phages inject their chromosomes into a λ -lysogen, but repressor molecules (R) immediately turn off the genes of these "superinfecting" chromosomes, just as they turn off the genes of the prophage. Immunity is thus caused by the same repressor that maintains the prophage in its dormant state.

λ -Phage: from M Ptashne, A Genetic Switch
& K. Sheppen

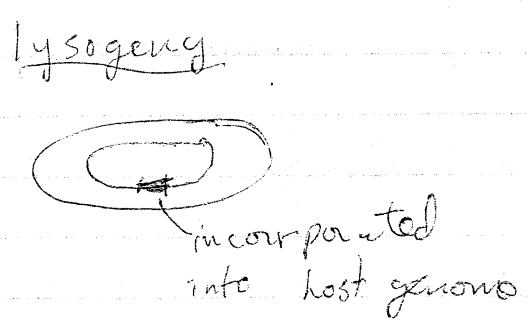

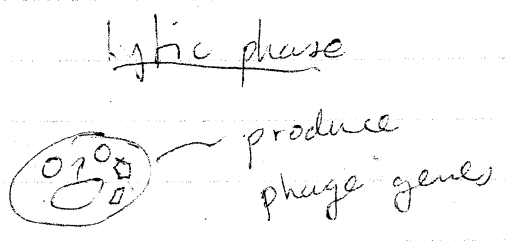

- λ -Phage, a specific virus that affects E. coli

- this is a switch in activity

★ Fig. 1 ★

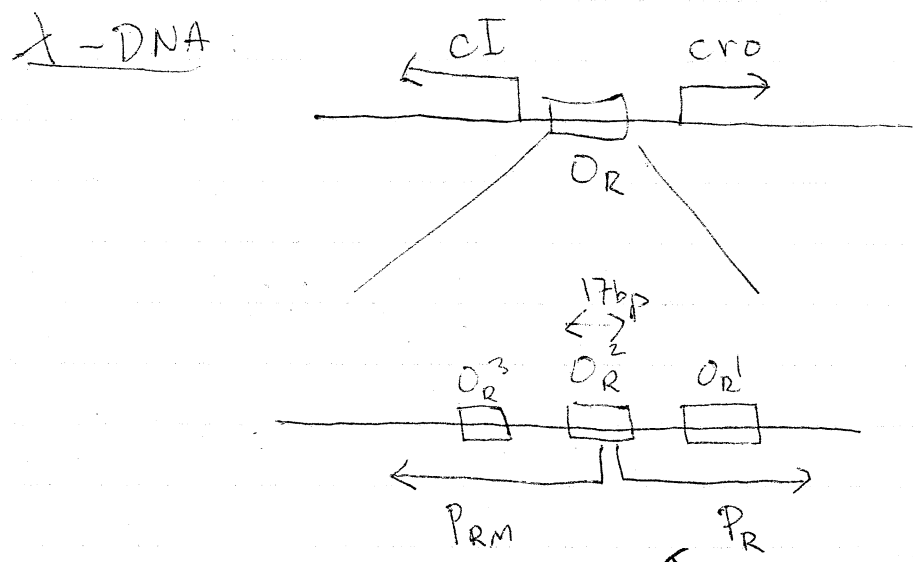

- show picture of phage - obligate parasite

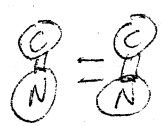

- Switched on by UV damage - detects ultimate demise of host \rightarrow GET OUT!!!

- In lysogen - λ -repressor is only gene that is produced \rightarrow turns off all other genes

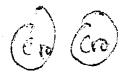

• UV \rightarrow λ -rep \rightarrow turns on Cro

- O_R 's all bind λ -rep & cro but @ diff't affinities
- P_R doesn't require an activator
- P_{RM} requires an activator

•  λ -rep forms dimers \rightarrow cooperativity

- dimer can bind any of 3 O_R sites

•  - cro also forms dimers

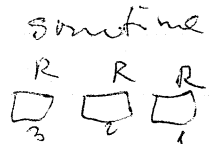

Switch:

• if O_R^2 occupied $\rightarrow P_R$ & \therefore no cro \rightarrow lysogen
 \rightarrow activates P_{RM} \rightarrow 10 fold \uparrow in cI

O_R^1 helps binding to O_R^2 +ve for RNAP

Reality: lysogen

O_I site affinity: $O_R^1 > O_R^2 > O_R^3$ & cooperativity btwn
 R 's @ O_R^1 & $O_R^2 \uparrow O_R^2$
 occupancy

no-coop btwn O_R^2 & O_R^3 since $O_R^2 \rightarrow O_R^1$
 w/ it
 no O_R^1 then O_R^3 & O_R^2 are cooperative

- Regulation of repressor:
 - O_R^3 acts as negative feedback
 - cI continually being diluted by cell growth & division
 - if cI level is too high then O_R^3 occupied $\rightarrow cI$ production

- Induction:
 - UV \rightarrow DNA damage \rightarrow turns on RecA ^{SOS response}
 - RecA cleaves λ -repressor cI _{DNA repair}

result: gradual decrease in binding to O_R^1 & O_R^2 by $cI \rightarrow$ cro gets transcribed!

- cro binds independently & $O_R^3 > O_R^2 > O_R^1$
 \rightarrow turns on cro & other genes \rightarrow eventually acts as -ve feedback

Switching & cooperativity

ineffective switch, in fact only single stable state, more on that later

What sets the lysis-lysogeny decision?

40,000 bp

Very early: N & cro are on

Early: + recomb & rep genes

$N \rightarrow cII$

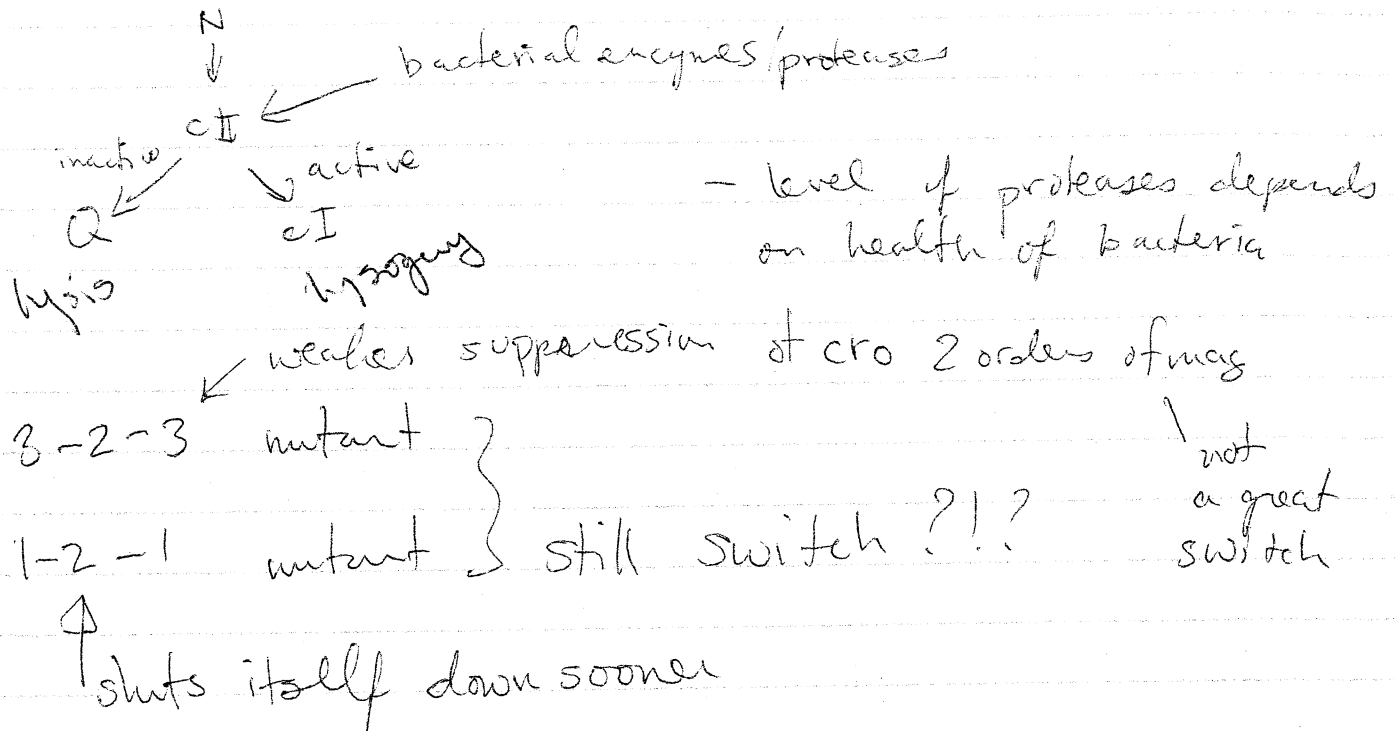

Late: 1) early genes off & head, tail + lysis \rightarrow lytic

2) cI & int \equiv recomb \rightarrow puts in host \equiv lysogen

Lytic: controlled by Q

Lysogenic: cII turns on cI & int, hence in absence of cI , cII will turn on cI which will then stimulate its own synthesis

Decision: affected by cII - activity determined by environment

- CII attacked by proteases @ are more active in starving cells
- $k_{II} = .6 \text{ kcal/mol}$

$$P = \frac{1}{1 + n_t/n} = \frac{n}{n + n_t} = \frac{n/n_t}{1 + n/n_t}$$

1-Phase: (just look @ cI)

$$x = [cI]$$

Simple: $\frac{dx}{dt} = \frac{\alpha x}{K+x} - \gamma x$ (no coop)

Cooperativity: 2 interacting binding sites

$$\frac{dx}{dt} = \frac{\alpha x^2}{K_0^2 + x^2} - \gamma x$$

\Rightarrow possibility for 2 stable states!

What about lac operon? From A. van Oudenaarden

only single site!

Repressor:

$$\frac{R}{R_T} = \frac{1}{K_x^n + x^n}$$

← shutting down of lact due to binding all-lactose

$$\frac{dy}{dt} = \frac{\alpha}{K_R + R} - \delta y \quad (\text{no-coop})$$

$$\frac{dx}{dt} = \beta y - \mu x \quad (\text{uptake})$$

- x uptake is fast & @ equilibrium

$$\Rightarrow x = \beta' y$$

so

$$R = \frac{R_T}{K_x^n + (\beta' y)^n}$$

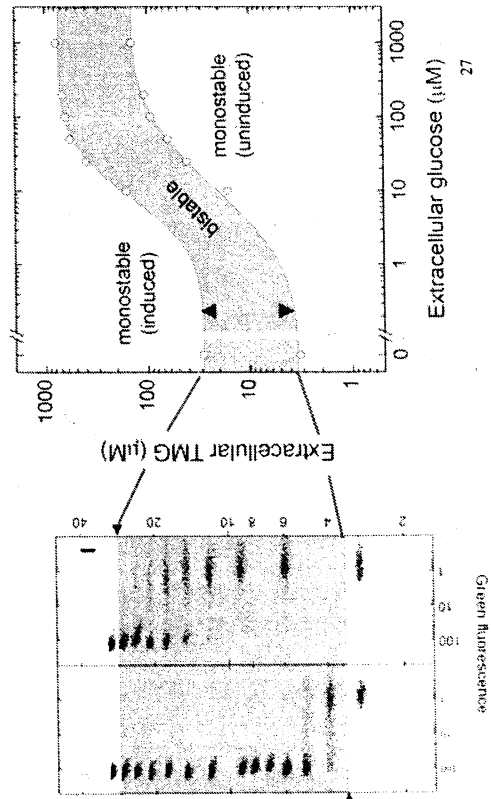

$$\Rightarrow \frac{dy}{dt} = \frac{\alpha' (1 + \beta' y)^n}{\beta + (\beta' y)^n} - y ; n \leq 2$$

∴ switchable

LacY hysteresis

Mapping the bistable region as a function of TMG and glucose concentration

Functions α , β , and ρ are calculated from switching thresholds

$$\left\{ \begin{aligned} \frac{R}{R_T} &= \frac{1}{1 + (x/x_0)^n} \\ \frac{dy}{dt} &= \alpha \frac{1}{1 + R/R_0} - \gamma \\ \frac{dx}{dt} &= \beta y - x \\ \rho &= 1 + R_T/R_0 \end{aligned} \right.$$

α : maximum lacY synthesis rate
obtained if $R \rightarrow 0$
 α / ρ : minimum lacY synthesis rate
obtained if $R \rightarrow R_T$

Stability Analysis

S. Strogatz Nonlinear Dynamics & Chaos

1D $\frac{dy}{dt} = f(y)$ & $f(y^*) = 0$

is y^* stable?

$$y = y^* + \delta y$$

$$\Rightarrow \delta \dot{y} = f'(y^*) \delta y \quad (\text{Taylor})$$

assume $\delta y = A \exp(\lambda t)$

$$\text{so } \lambda \delta y = f'(y^*) \delta y$$

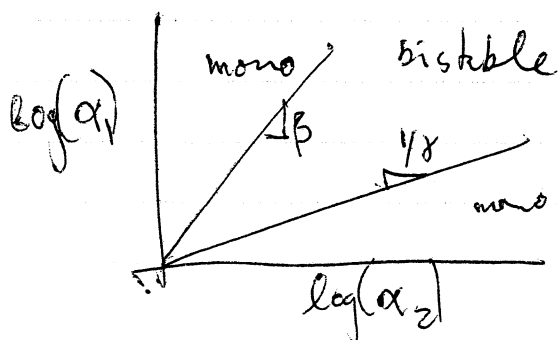

$$(f'(y^*) - \lambda) \delta y = 0$$

$$\text{so } \lambda = f'(y^*)$$

$$\text{if } \lambda < 0$$
$$\lambda > 0$$

then decays & is stable
unstable

2D Want to derive Fig 2cd bifurcations

2D $\dot{x} = f(x, y)$
 $\dot{y} = g(x, y)$

nullclines $\dot{x} = 0$ & $\dot{y} = 0 \Rightarrow f(x_0, y_0) = 0$ & $g(x_0, y_0) = 0$

linearize:

$\delta \vec{x} = x - x_0$ & $\delta y = y - y_0$

$\dot{x} = \delta \dot{x} = \delta x \frac{\partial f}{\partial x} \Big|_{x_0, y_0} + \delta y \frac{\partial f}{\partial y} \Big|_{x_0, y_0} = a \delta x + b \delta y$

$\dot{y} = \delta \dot{y} = \delta x \frac{\partial g}{\partial x} \Big|_{x_0, y_0} + \delta y \frac{\partial g}{\partial y} \Big|_{x_0, y_0} = c \delta x + d \delta y$

or

$\delta \dot{\vec{x}} = A \delta \vec{x}$ where $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \equiv \text{Jacobian}$

$A_{ij} = \frac{\partial f^i}{\partial x_j}$; $\tau = \text{Tr}(A) = a + d$
 $\Delta = \det(A) = ad - cb$

Consider ~~with $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ & $\Delta = \det(A) = ad - cb$~~

$\delta \vec{x}_0 = \vec{a} e^{t}$ $\delta \vec{x} = \sum c_i \vec{a}_i e^{t_i t}$

$\Rightarrow A \delta \vec{x} = \lambda \delta \vec{x}$

\Rightarrow eigenvalue problem

$$\det \begin{bmatrix} a-\lambda & b \\ c & d-\lambda \end{bmatrix}$$

$$\Rightarrow \lambda_1 = \frac{\tau + \sqrt{\tau^2 - 4\Delta}}{2}$$

$$\Delta = ad - bc$$

$$\tau = a + d$$

$$\lambda_2 = \frac{\tau - \sqrt{\tau^2 - 4\Delta}}{2}$$

diagonal: $\Delta = \lambda_1 \lambda_2$ & $\tau = \lambda_1 + \lambda_2$

for stability require $\lambda_i < 0$

so must have $\Delta > 0$ & $\tau < 0$ (for 2D)

Collins:

$$\dot{u} = \frac{\alpha_1}{1 + \nu^\beta} - u = f(u, \nu)$$

$$\dot{\nu} = \frac{\alpha_2}{1 + u^\gamma} - \nu = g(u, \nu)$$

fixed points

$$u = \frac{\alpha_1}{1 + \nu^\beta}$$

$$\nu = \frac{\alpha_2}{1 + u^\gamma}$$

$$A = \begin{bmatrix} -1 & \frac{-\alpha_1 \beta v^{\beta-1}}{(1+v^\beta)^2} \\ \frac{-\alpha_2 \gamma u^{\gamma-1}}{(1+u^\gamma)^2} & -1 \end{bmatrix}$$

• $\tau < 0$ good!

• $\Delta = 0$ gives boundary

$$\Rightarrow \frac{\alpha_1 \beta v^{\beta-1}}{(1+v^\beta)^2} \frac{\alpha_2 \gamma u^{\gamma-1}}{(1+u^\gamma)^2} = 1$$

use fixed point eqns for u & v

$$\Rightarrow \beta \gamma v^{\beta+1} u^{\gamma+1} = \alpha_1 \alpha_2$$

for large α_1 & α_2 & for high state $u \gg v$

$$\text{so } u \approx \alpha_1 \text{ \& } v \approx \alpha_2 / \alpha_1$$

$$\text{so } \beta \gamma \alpha_2^\beta \alpha_1^{-\beta \gamma} = 1 \quad \& \text{ symmetry } \beta \gamma \alpha_1^\gamma \alpha_2^{-\beta \gamma} = 1$$

or $\log(\alpha_1) \approx \frac{1}{\gamma} \log \alpha_2$ (straight line with slope $1/\gamma$)
