Solution: Given $\Delta \mathrm{p}=\mathrm{fcn}(\rho, \mathrm{V}, \mathrm{d} / \mathrm{D})$, then by dimensional analysis $\Delta \mathrm{p} /\left(\rho \mathrm{V}^{2}\right)=\mathrm{fcn}(\mathrm{d} / \mathrm{D})$. For water at $20^{\circ} \mathrm{C}$, take $\rho=998 \mathrm{~kg} / \mathrm{m}^{3}$. For gasoline at $20^{\circ} \mathrm{C}$, take $\rho=680 \mathrm{~kg} / \mathrm{m}^{3}$. Then, using the water 'model' data to obtain the function " $\mathrm{fcn}(\mathrm{d} / \mathrm{D})$ ", we calculate

$$
\frac{\Delta \mathrm{p}_{\mathrm{m}}}{\rho_{\mathrm{m}} \mathrm{~V}_{\mathrm{m}}^{2}}=\frac{5000}{(998)(4.0)^{2}}=0.313=\frac{\Delta \mathrm{p}_{\mathrm{p}}}{\rho_{\mathrm{p}} \mathrm{~V}_{\mathrm{p}}^{2}}=\frac{15000}{(680) \mathrm{V}_{\mathrm{p}}^{2}}, \text { solve for } \mathrm{V}_{\mathrm{p}} \approx 8.39 \frac{\mathrm{~m}}{\mathrm{~s}}
$$

Given $\mathrm{Q}=\frac{9}{60} \frac{\mathrm{~m}^{3}}{\mathrm{~s}}=\mathrm{V}_{\mathrm{p}} \mathrm{A}_{\mathrm{p}}=(8.39) \frac{\pi}{4} \mathrm{D}_{\mathrm{p}}^{2}$, solve for best $\mathbf{D}_{\mathrm{p}} \approx \mathbf{0 . 1 5 1} \mathrm{m}$ Ans.
5.72 A one-fifteenth-scale model of a parachute has a drag of 450 lbf when tested at $20 \mathrm{ft} / \mathrm{s}$ in a water tunnel. If Reynolds-number effects are negligible, estimate the terminal fall velocity at $5000-\mathrm{ft}$ standard altitude of a parachutist using the prototype if chute and chutist together weigh 160 lbf . Neglect the drag coefficient of the woman.

Solution: For water at $20^{\circ} \mathrm{C}$, take $\rho=1.94 \mathrm{~kg} / \mathrm{m}^{3}$. For air at $5000-\mathrm{ft}$ standard altitude (Table A-6) take $\rho=0.00205 \mathrm{~kg} / \mathrm{m}^{3}$. If Reynolds number is unimportant, then the two cases have the same drag-force coefficient:

$$
\begin{gathered}
\mathrm{C}_{\mathrm{Dm}}=\frac{\mathrm{F}_{\mathrm{m}}}{\rho_{\mathrm{m}} \mathrm{~V}_{\mathrm{m}}^{2} \mathrm{D}_{\mathrm{m}}^{2}} \\
=\frac{450}{1.94(20)^{2}\left(\mathrm{D}_{\mathrm{p}} / 15\right)^{2}}=\mathrm{C}_{\mathrm{Dp}}=\frac{160}{0.00205 \mathrm{~V}_{\mathrm{p}}^{2} \mathrm{D}_{\mathrm{p}}^{2}}, \\
\text { solve } \quad \mathbf{V}_{\mathrm{p}} \approx \mathbf{2 4 . 5} \frac{\mathbf{f t}}{\mathbf{s}} \text { Ans. }
\end{gathered}
$$

5.73 The power $P$ generated by a certain windmill design depends upon its diameter $D$, the air density $\rho$, the wind velocity $V$, the rotation rate $\Omega$, and the number of blades $n$. (a) Write this relationship in dimensionless form. A model windmill, of diameter 50 cm , develops 2.7 kW at sea level when $V=40 \mathrm{~m} / \mathrm{s}$ and when rotating at $4800 \mathrm{rev} / \mathrm{min}$. (b) What power will be developed by a geometrically and dynamically similar prototype, of diameter 5 m , in winds of 12 $\mathrm{m} / \mathrm{s}$ at 2000 m standard altitude? (c) What is the appropriate rotation rate of the prototype?

Solution: (a) For the function $P=\operatorname{fcn}(D, \rho, V, \Omega, n)$ the appropriate dimensions are $\{P\}=$ $\left\{\mathrm{ML}^{2} \mathrm{~T}^{-3}\right\},\{D\}=\{\mathrm{L}\},\{\rho\}=\left\{\mathrm{ML}^{-3}\right\},\{V\}=\{\mathrm{L} / \mathrm{T}\},\{\Omega\}=\left\{\mathrm{T}^{-1}\right\}$, and $\{n\}=\{1\}$. Using $(D, \rho$, $V$ ) as repeating variables, we obtain the desired dimensionless function:

$$
\frac{P}{\rho D^{2} V^{3}}=f c n\left(\frac{\Omega D}{V}, n\right) \text { Ans. (a) }
$$
