Figure: Picture taken from the International Space Station (ISS) in February, 2013. It shows the north coast of the island of Trinidad in the southeastern Caribbean Sea and the huge internal waves that are visible in the top left. Image credit: NASA/JPL.

- ▶ Internal waves play an important role in ocean circulation. Generated by tides and winds, they propagate through the oceans and seas, redistributing momentum and energy before dissipating.
- ▶ Topography of the ocean floor may play a role in dissipation and [generation of internal wave attractors](#).

- ▶ Usual simplification: non-rotating, linearly stratified fluid.
- ▶ Extensively studied in 2D: Maas & Lam '95, Ogilvie '05, Lam & Maas '08, Rieutord, Georgeot & Valdetaro '01.
- ▶ And in 3D: Manders & Mass '03, Drijfhout & Maas '07, [Pillet et. al. '18](#).

Figure: **L**: Experimental setting. **R**: A internal ray beam path leads to an attractor in a plane transverse to the along-slope, down-canal direction into which rays are initially launched. Source: [Pillet et. al., JFM 2018](#).

Figure: **L:** (Filtered) Velocity amplitudes at different slices of the tank obtained by Particle Image Velocimetry (PIV). **R:** The attractor at $x = 250$ mm, with the superimposed ray tracing prediction.

Main ingredients and simplifications:

- ▶ Linearly stratified fluid with density $\bar{\rho}$, small perturbations η ,
- ▶ Incompressible fluid ($\nabla \cdot \mathbf{u} = 0$) and no-flux BC,
- ▶ (Linearized) Conservation of mass:

$$\partial_t \eta + \mathbf{u} \cdot \nabla \bar{\rho} = 0,$$

- ▶ (Linearized) Conservation of momentum:

$$\bar{\rho} \partial_t \mathbf{u} + \eta g \mathbf{e}_3 + \nabla \Pi = \mathbf{F} e^{-i\omega_0 t},$$

Main ingredients and simplifications:

- ▶ Domain: 2-torus
- ▶ Symbol: $\tilde{p}(z, \xi) \rightarrow \frac{\xi_3}{|\xi|} - r\beta(y, z)$ (to account for topography).

$$i\partial_t u - P(x, D)u = fe^{-i\omega_0 t} \quad \text{in } \mathbb{T}^2 \times (0, T], \quad u|_{t=0} = 0,$$

- ▶ $u = u(x, t)$, periodic BC
- ▶ $P(x, D)$ self-adjoint pseudo-differential operator,
- ▶ The symbol $p(x, \xi)$ is homogeneous of degree 0, of form

$$p(x, \xi) = \frac{\xi_2}{\sqrt{1 + |\xi|^2}} - \text{periodic function.}$$

We would like to figure out:

$$i\partial_t u - P(x, D)u = fe^{-i\omega_0 t} \quad \text{in } \mathbb{T}^2 \times (0, T], \quad u|_{t=0} = 0,$$

- ▶ $u = u(x, t)$, periodic BC
- ▶ $P(x, D)$ self-adjoint pseudo-differential operator,
- ▶ The symbol $p(x, \xi)$ is homogeneous of degree 0, of form

$$p(x, \xi) = \frac{\xi_2}{\sqrt{1 + |\xi|^2}} - \text{periodic function.}$$

We would like to figure out:

- ▶ What is the long-time behaviour of solutions?

$$i\partial_t u - P(x, D)u = fe^{-i\omega_0 t} \quad \text{in } \mathbb{T}^2 \times (0, T], \quad u|_{t=0} = 0,$$

- ▶ $u = u(x, t)$, periodic BC
- ▶ $P(x, D)$ self-adjoint pseudo-differential operator,
- ▶ The symbol $p(x, \xi)$ is homogeneous of degree 0, of form

$$p(x, \xi) = \frac{\xi_2}{\sqrt{1 + |\xi|^2}} - \text{periodic function.}$$

We would like to figure out:

- ▶ What is the long-time behaviour of solutions?
- ▶ What is the spectrum of P ?

$$i\partial_t u - P(x, D)u = fe^{-i\omega_0 t} \quad \text{in } \mathbb{T}^2 \times (0, T], \quad u|_{t=0} = 0,$$

- ▶ $u = u(x, t)$, periodic BC
- ▶ $P(x, D)$ self-adjoint pseudo-differential operator,
- ▶ The symbol $p(x, \xi)$ is homogeneous of degree 0, of form

$$p(x, \xi) = \frac{\xi_2}{\sqrt{1 + |\xi|^2}} - \text{periodic function.}$$

We would like to figure out:

- ▶ What is the long-time behaviour of solutions?
- ▶ What is the spectrum of P ?
- ▶ Does the spectrum of P affect the long-term evolution?

- ▶ Fourth-order explicit method in time,
- ▶ Fourier collocation method in space,
- ▶ In particular, the operator $Q(x, D)$ of symbol $q(x, \xi) = (1 + |\xi|^2)^{-1/2} \xi_2$ is discretized as

$$Q(x, D)w \approx \mathcal{F}^{-1} \left(\text{diag} \left(\frac{k_2}{\sqrt{1 + |k|^2}} \right) \mathcal{F} w_N \right)$$

where $\mathcal{F}$ is the discrete Fourier transform and w_N corresponds to w evaluated at the N^2 grid points in real space.

Theorem (Colin de Verdière-Saint Raymond '20, Dyatlov-Zworski '20)

Let P be a self-adjoint, pseudo-differential operator of order zero and $\omega_0 \notin \text{Spec}_{pp}(P)$. Then, under certain additional assumptions on P , for any $f \in C^\infty(\mathbb{T}^2)$, the solution u to the evolution problem satisfies

$$u(t) = e^{-i\omega_0 t} u_\infty + b(t) + \epsilon(t),$$

where

- ▶ $u_\infty = \lim_{\varepsilon \rightarrow 0} (P - \omega_0 - i\varepsilon)^{-1} f \in \mathcal{H}^{-1/2-} := \cap_{\delta > 0} \mathcal{H}^{-1/2-\delta}(\mathbb{T}^2)$ and **is not** in $L^2(\mathbb{T}^2)$ except if it vanishes,
- ▶ $\|b(t)\|_{L^2(\mathbb{T}^2)} < \infty$,
- ▶ $\epsilon(t) \rightarrow 0$ as $t \rightarrow \infty$ in $H^{-1/2-}$.

Figure: Attractors and linear evolution of the squared L^2 -norm. The forcing is a centered Gaussian, $r = 0.25$ and $\beta(x) = \cos(x_1) + \sin(x_2)$. Video available at youtu.be/3b5UQfRcyEk.

Figure: Attractors and linear evolution of the squared L^2 -norm. The forcing is a centered Gaussian, $r = 0.25$ and $\beta(x) = \cos(x_1) + \sin(x_2)$. Video available at youtu.be/3b5UQfRcyEk.

Theorem (cont.)

Moreover, for $t > 0$, $\|u(t)\|_{L^2(\mathbb{T}^2)}^2 \sim ct$ except if u_∞ vanishes.

- How the Fourier coefficients of $u_N(t)$ decay? $\rightarrow$ Radial Energy Density

$$G_s(R) = \frac{1}{N^2} \sum_{k \in A_R \cap \mathbb{Z}^2} (1 + |k|^2)^s |\widehat{u}_N(k)|^2, \quad A_R = \{x \in \mathbb{R}^2 : R \leq |x| < R+2\}.$$

Figure: If a distribution $v \in \mathcal{H}^S$, then the radial energy density G_S should decay faster than $\mathcal{O}(R^{-1})$ as $R \rightarrow \infty$.

Figure: Radial energy density as $T \rightarrow \infty$. Top: $s = -0.7$. Bottom: $s = -1.5$.

Theorem (Colin de Verdière '20)

Let $J := [\min p, \max p]$, where p is the symbol of P . Then,

1. $\sigma_{\text{ess}}(P) = J$,
2. P has a finite number of eigenvalues in J and they have finite multiplicity.

Theorem (Colin de Verdière '20)

Let $J := [\min p, \max p]$, where p is the symbol of P . Then,

1. $\sigma_{\text{ess}}(P) = J$,
2. P has a finite number of eigenvalues in J and they have finite multiplicity.

Theorem (Galkowski-Zworski '19)

Under certain assumptions on P , there exists an open neighbourhood of 0 in $\mathbb{C}$, U and a set

$$\mathcal{R}(P) \subset \{\operatorname{Im}(z) \leq 0\} \cap U$$

such that for every compact set $K \subset U$, $\mathcal{R}(P) \cap K$ is discrete, and

$$\operatorname{spec}_{L^2}(P + i\nu\Delta) \longrightarrow \mathcal{R}(P), \quad \nu \rightarrow 0+,$$

uniformly on K . Moreover,

$$\mathcal{R}(P) \cap \mathbb{R} = \operatorname{spec}_{pp, L^2}(P) \cap U.$$

Figure: Superposition of the first 200 eigenvalues (ordered by magnitude, then phase) for several values of ν decreasing until $\nu = 10^{-3}$. Each color represents a position in the vector of eigenvalues. As ν decreases, eigenvalues move up to the real axis. Video available at youtu.be/qeNRxWSptuo.

$$p(x, \xi) = \frac{\xi_2}{\sqrt{1 + |\xi|^2}} - 0.5 \left(\cos(x_1) + \sin(x_2) \right)$$

Figure: **L**: Solution to the evolution problem. **R**: First 4 eigenfunctions of the viscous approximation, $\nu = 10^{-3}$.

$$p(x, \xi) = \frac{\xi_2}{\sqrt{1 + |\xi|^2}} - 2 \cos(x_1)$$

Figure: **L**: Solution to the evolution problem. **R**: First 4 eigenfunctions of the viscous approximation, $\nu = 10^{-4}$.

$$p(x, \xi) = \frac{\xi_2}{\sqrt{1 + |\xi|^2}} - 0.55 \left(\cos(x_1 - 2x_2) + \sin(2x_2) \right)$$

Figure: **L**: Solution to the evolution problem. **R**: First 4 eigenfunctions of the viscous approximation, $\nu = 1.5 \cdot 10^{-4}$.

- ▶ An evolution problem with solutions that live in Sobolev spaces of negative exponent,
- ▶ Numerical evidence that some of the eigenmodes in the small-viscosity limit converge to embedded eigenmodes, which impact long-term evolution,
- ▶ A lot remains to be said at a theoretical level!
