## Expectation

Richard Lockhart

Simon Fraser University

STAT 801=830 — Fall 2012

# What I assume you already know

- Continuous case:  $E(X) = \int_{-\infty}^{\infty} xf(x) dx$ .
- Discrete case:  $E(X) = \sum_x xf(x)$
- Mean, variance, standard deviation, covariance, correlation.
- Conditional analogues of above.

# What I want you to learn

- Abstract definition of  $E(X)$ .
- Dominated, monotone convergence theorems.
- Mean, variance, standard deviation, covariance, correlation.
- Define conditional expectation and relation to conditional density.
- Give some properties of conditional expectation.

- Two elementary definitions of expected values:
- **Def'n:** If  $X$  has density  $f$  then

$$E\{g(X)\} = \int g(x)f(x) dx.$$

- **Def'n:** If  $X$  has discrete density  $f$  then

$$E\{g(X)\} = \sum_x g(x)f(x).$$

- **FACT:** if  $Y = g(X)$  for a smooth  $g$

$$\begin{aligned} E(Y) &= \int yf_Y(y) dy = \int g(x)f_Y(g(x))g'(x) dx \\ &= E\{g(X)\} \end{aligned}$$

by change of variables formula for integration.

- Good: otherwise might have two different values for  $E(e^X)$ .

- There are random variables which are neither absolutely continuous nor discrete.
- **Def'n:** RV  $X$  is simple if we can write

$$X(\omega) = \sum_1^n a_i 1(\omega \in A_i)$$

for some constants  $a_1, \dots, a_n$  and events  $A_i$ .

- **Def'n:** For a simple rv  $X$  define

$$E(X) = \sum a_i P(A_i).$$

- For positive random variables which are not simple extend definition by approximation:
- **Def'n:** If  $X \geq 0$  then

$$E(X) = \sup\{E(Y) : 0 \leq Y \leq X, Y \text{ simple}\}.$$

# Integrable rvs

- **Def'n:**  $X$  is **integrable** if

$$E(|X|) < \infty.$$

- In this case we define

$$E(X) = E\{\max(X, 0)\} - E\{\max(-X, 0)\}.$$

- Facts:  $E$  is a linear, monotone, positive operator:
  - 1 **Linear:**  $E(aX + bY) = aE(X) + bE(Y)$  provided  $X$  and  $Y$  are integrable.
  - 2 **Positive:**  $P(X \geq 0) = 1$  implies  $E(X) \geq 0$ .
  - 3 **Monotone:**  $P(X \geq Y) = 1$  and  $X, Y$  integrable implies  $E(X) \geq E(Y)$ .

# Convergence Theorems

- Major technical theorems:
- **Monotone Convergence:** If  $0 \leq X_1 \leq X_2 \leq \dots$  and  $X = \lim X_n$  (which has to exist) then

$$E(X) = \lim_{n \rightarrow \infty} E(X_n).$$

- **Dominated Convergence:** If  $|X_n| \leq Y_n$  and  $\exists$  rv  $X$  such that  $X_n \rightarrow X$  (technical details of this convergence later in the course) and a random variable  $Y$  such that  $Y_n \rightarrow Y$  with  $E(Y_n) \rightarrow E(Y) < \infty$  then

$$E(X_n) \rightarrow E(X).$$

- Often used with all  $Y_n$  the same rv  $Y$ .
- These theorems are used in *approximation*.

## Connection to integration

With this definition of  $E$ :

- 1 if  $X$  has density  $f(x)$  (even in  $R^p$  say) and  $Y = g(X)$  then

$$E(Y) = \int g(x)f(x)dx.$$

(Could be a multiple integral.)

- 2 If  $X$  has pmf  $f$  then

$$E(Y) = \sum_x g(x)f(x).$$

- 3 First conclusion works, e.g., even if  $X$  has a density but  $Y$  doesn't.

- **Def'n:** The  $r^{\text{th}}$  moment (about the origin) of a real rv  $X$  is  $\mu'_r = E(X^r)$  (provided it exists).
- We generally use  $\mu$  for  $E(X)$ .
- **Def'n:** The  $r^{\text{th}}$  central moment is

$$\mu_r = E[(X - \mu)^r]$$

- We call  $\sigma^2 = \mu_2$  the variance.
- **Def'n:** For an  $R^p$  valued random vector  $X$

$$\mu_X = E(X)$$

is the vector whose  $i^{\text{th}}$  entry is  $E(X_i)$  (provided all entries exist).

- **Def'n:** The  $(p \times p)$  variance covariance matrix of  $X$  is

$$\text{Var}(X) = E [(X - \mu)(X - \mu)^t]$$

which exists provided each component  $X_i$  has a finite second moment

# Moments and independence

If  $X_1, \dots, X_p$  are independent and each  $X_i$  is integrable then  $X = X_1 \cdots X_p$  is integrable and

$$E(X_1 \cdots X_p) = E(X_1) \cdots E(X_p).$$

## Proof

Suppose each  $X_i$  is simple:

$$X_i = \sum_j x_{ij} 1(X_i = x_{ij})$$

where the  $x_{ij}$  are the possible values of  $X_i$ . Then

$$\begin{aligned} E(X_1 \cdots X_p) &= \sum_{j_1 \cdots j_p} x_{1j_1} \cdots x_{pj_p} E(1(X_1 = x_{1j_1}) \cdots 1(X_p = x_{pj_p})) \\ &= \sum_{j_1 \cdots j_p} x_{1j_1} \cdots x_{pj_p} P(X_1 = x_{1j_1} \cdots X_p = x_{pj_p}) \\ &= \sum_{j_1 \cdots j_p} x_{1j_1} \cdots x_{pj_p} P(X_1 = x_{1j_1}) \cdots P(X_p = x_{pj_p}) \\ &= \sum_{j_1} x_{1j_1} P(X_1 = x_{1j_1}) \cdots \sum_{j_p} x_{pj_p} P(X_p = x_{pj_p}) \\ &= \prod E(X_i). \end{aligned}$$

## General Case

- General  $X_i \geq 0$ :
- Let  $X_{in}$  be  $X_i$  rounded down to nearest multiple of  $2^{-n}$  (to maximum of  $n$ ).
- That is: if

$$\frac{k}{2^n} \leq X_i < \frac{k+1}{2^n}$$

then  $X_{in} = k/2^n$  for  $k = 0, \dots, n2^n$ .

- For  $X_i > n$  put  $X_{in} = n$ .
- Apply case just done:

$$E\left(\prod X_{in}\right) = \prod E(X_{in}).$$

- Monotone convergence applies to both sides.
- General case: write each  $X_i$  as difference of positive and negative parts:

$$X_i = \max(X_i, 0) - \max(-X_i, 0).$$

- Apply positive case.

- Abstract definition of conditional expectation is:
- **Def'n:**  $E(Y|X)$  is any function of  $X$  such that

$$E [R(X)E(Y|X)] = E [R(X)Y]$$

for any bounded function  $R(X)$ .

- **Def'n:**  $E(Y|X = x)$  is a function  $g(x)$  such that

$$g(X) = E(Y|X)$$

- **Fact:** If  $X, Y$  has joint density  $f_{X,Y}(x, y)$  and conditional density  $f(y|x)$  then

$$g(x) = \int yf(y|x)dy$$

satisfies these definitions.

# Proof

$$\begin{aligned} E(R(X)g(X)) &= \int R(x)g(x)f_X(x)dx \\ &= \int R(x) \int yf(y|x)dyf_X(x)dx \\ &= \int \int R(x)yf_X(x)f(y|x)dydx \\ &= \int \int R(x)yf_{X,Y}(x,y)dydx \\ &= E(R(X)Y) \end{aligned}$$

## Interpretation of conditional expectation

- **Intuition:** Think of  $E(Y|X)$  as average  $Y$  holding  $X$  fixed.
- Behaves like ordinary expected value but functions of  $X$  only are like constants:

$$E\left(\sum A_i(X)Y_i|X\right) = \sum A_i(X)E(Y_i|X)$$

- Statement called Adam's law by Jerzy Neyman – he used to say it comes before all the others:

$$E[E(Y|X)] = E(Y)$$

which is just the definition of  $E(Y|X)$  with  $R(X) \equiv 1$ .

- In regression courses we say that the total sum of squares is the sum of the regression sum of squares plus the residual sum of squares:

$$\text{Var}(Y) = \text{Var}(E(Y|X)) + E[\text{Var}(Y|X)]$$

- The conditional variance means

$$\text{Var}(Y|X) = E[(Y - E(Y|X))^2|X].$$
