Wave Motion

Key points:

- **Types of Waves: Transverse and Longitudinal**
- **Mathematical Representation of a Traveling Wave**
- **The Principle of Superposition**
- **Standing Waves; Resonance**

Ref: 11-7,8,9,10,11,16,12,13,16.

Characteristics of Wave Motion

When a vibration propagates, we have a wave.

Characteristics of Wave Motion

- Amplitude, A
- Wavelength, λ
- Frequency, f and period, T
- Wave velocity, $v = \lambda f$

Types of Waves: Transverse and Longitudinal

The motion of particles in a wave can be either perpendicular to the wave direction (transverse) or parallel to it (longitudinal).

Types of Waves: Transverse and Longitudinal

Sound waves are longitudinal waves:

Types of Waves: Transverse and Longitudinal

The velocity of a transverse wave on a cord is given by:

$$v = \sqrt{\frac{F_T}{\mu}}$$

Where F_T is the tension in the cord and μ is the linear density (mass per unit length, $\mu=m/L$).

As expected, the velocity increases when the tension increases, and decreases when the mass increases.

Types of Waves: Transverse and Longitudinal

The velocity of a longitudinal wave depends on the elastic restoring force of the medium and on the mass density.

$$v = \sqrt{\frac{E}{\rho}} \quad \text{For a solid rod.}$$

or

$$v = \sqrt{\frac{B}{\rho}}. \quad \text{For fluids}$$

E – Young's Modulus;

B – Bulk modulus.

Example: Echolocation.

Echolocation is a form of sensory perception used by animals such as bats, toothed whales, and dolphins. The animal emits a pulse of sound (a longitudinal wave) which, after reflection from objects, returns and is detected by the animal. Echolocation waves can have frequencies of about 100,000 Hz. (a) Estimate the wavelength of a sea animal's echolocation wave. (b) If an obstacle is 100 m from the animal, how long after the animal emits a wave is its reflection detected?

(a)

$$\lambda = \frac{v}{f} \quad \text{where} \quad v = \sqrt{\frac{B}{\rho}} = \sqrt{\frac{2.0 \times 10^9}{1025}} = 1.4 \times 10^3 \text{ m/s}$$

$$\lambda = \frac{v}{f} = \frac{1.4 \times 10^3}{10^5} = 1.4 \times 10^{-2} \text{ m}$$

(b)

$$t = \frac{d}{v} = \frac{2 \times 100}{1.4 \times 10^3} = 0.14 \text{ s}$$

Energy Transported by Waves

By looking at the energy of a particle of matter in the medium of a wave, we find:

$$E = \frac{1}{2}kA^2 = 2\pi^2mf^2A^2.$$

Then, assuming the entire medium has the same density, the power (energy through S per unit time) is

$$\bar{P} = 2\pi^2(\rho Sl)f^2A^2 / t = 2\pi^2\rho Sv f^2A^2$$

The intensity (power per unit area) is

$$I = \frac{\bar{P}}{S} = 2\pi^2v\rho f^2A^2.$$

The intensity is proportional to the square of the frequency and to the square of the amplitude.

Energy Transported by Waves

If a wave is able to spread out three-dimensionally from its source, and the medium is uniform, the wave is **spherical**.

Just from geometrical considerations, as long as the power output is **constant**, we see:

$$I \propto \frac{1}{r^2}.$$

Total power at r_1 and r_2 : $P_1 = P_2 = P_0$

$$\text{Intensity at } r_1 : I_1 = \frac{P_1}{4\pi r_1^2} = \frac{P_0}{4\pi r_1^2}$$

$$\text{Intensity at } r_2 : I_2 = \frac{P_2}{4\pi r_2^2} = \frac{P_0}{4\pi r_2^2}$$

$\therefore$ Intensity at r :

$$I = \frac{P_0}{4\pi r^2} \propto \frac{1}{r^2}$$

Example: Earthquake intensity.

The intensity of an earthquake P wave traveling through the Earth and detected 100 km from the source is $1.0 \times 10^6 \text{ W/m}^2$. What is the intensity of that wave if detected 400 km from the source?

$$I_1 = \frac{P_0}{4\pi r_1^2}, \quad I_2 = \frac{P_0}{4\pi r_2^2}$$

$$\frac{I_2}{I_1} = \frac{r_1^2}{r_2^2}$$

$$I_2 = \frac{r_1^2}{r_2^2} I_1 = \frac{(1.0 \times 10^5)^2}{(4.0 \times 10^5)^2} (1.0 \times 10^6) = 6.25 \times 10^4 \text{ W / m}^2$$

Mathematical Representation of a Traveling Wave

Suppose the shape of a wave is given by:

$$D(x) = A \sin \frac{2\pi}{\lambda} x.$$

Mathematical Representation of a Traveling Wave

After a time t , the wave crest has traveled a distance vt , so we write:

$$D(x, t) = A \sin \left[\frac{2\pi}{\lambda} (x - vt) \right].$$

Or: $D(x, t) = A \sin(kx - \omega t),$

with $\omega = 2\pi f, \quad k = \frac{2\pi}{\lambda}.$

$$\omega = kv \quad \text{or} \quad v = \frac{\omega}{k}$$

Example: A traveling wave.

The left-hand end of a long horizontal stretched cord oscillates transversely in SHM with frequency $f = 250$ Hz and amplitude 2.6 cm. The cord is under a tension of 140 N and has a linear density $\mu = 0.12$ kg/m. At $t = 0$, the end of the cord has an upward displacement of 1.6 cm and is falling. Determine (a) the wavelength of waves produced and (b) the equation for the traveling wave.

The Principle of Superposition

Superposition: The displacement at any point is the vector sum of the displacements of all waves passing through that point at that instant.

Fourier's theorem: Any complex periodic wave can be written as the sum of sinusoidal waves of different amplitudes, frequencies, and phases.

Interference

These graphs show the sum of two waves. In (a) they add **constructively**; in (b) they add **destructively**; and in (c) they add **partially destructively**.

Standing Waves; Resonance

Standing waves occur when both ends of a string are fixed. In that case, only waves which are motionless at the ends of the string can persist. There are nodes, where the amplitude is always zero, and antinodes, where the amplitude reaches the maximum value.

Standing Waves; Resonance

The frequencies of the standing waves on a particular string are called **resonant frequencies**.

They are also referred to as the **fundamental and harmonics**.

$$l = \frac{\lambda}{2} n$$

Fundamental or first harmonic, f_1

First overtone or second harmonic, $f_2 = 2f_1$

Second overtone or third harmonic, $f_3 = 3f_1$

The wavelengths and frequencies of standing waves are:

$$\lambda_n = \frac{2\ell}{n}, \quad n = 1, 2, 3, \dots,$$

$$f_n = \frac{v}{\lambda_n} = n \frac{v}{2\ell} = nf_1, \quad n = 1, 2, 3, \dots$$

Example: Piano string.

A piano string is 1.10 m long and has a mass of 9.00 g. (a) How much tension must the string be under if it is to vibrate at a fundamental frequency of 131 Hz? (b) What are the frequencies of the first four harmonics?

Example: Wave forms.

Two waves traveling in opposite directions on a string fixed at $x = 0$ are described by the functions

$$D_1 = (0.20 \text{ m})\sin(2.0x - 4.0t) \text{ and } D_2 = (0.20 \text{ m})\sin(2.0x + 4.0t)$$

(where x is in m, t is in s), and they produce a standing wave pattern. Determine (a) the function for the standing wave, (b) the maximum amplitude at $x = 0.45 \text{ m}$, (c) where the other end is fixed ($x > 0$), (d) the maximum amplitude, and where it occurs.
