## PHYS 4xx Poly 4 - Biopolymers

## Some important filaments in the cell

## DNA

- monomeric unit is phosphate + sugar + organic base
- phosphate and sugar units alternate along each strand of a double helix
- length along the helix is 0.34 nm per base pair; diameter is 2 nm

## Spectrin

- tetramer is two pairs of chains, joined end-to-end, total contour length of 200 nm
- pair has two intertwined and inequivalent ( $\alpha$ and $\beta$ ) strings of spectrin (pairs join end-to-end to form a tetramer)

- chain folds back on itself repeatedly, so that each monomer is a series of 19 or 20 relatively rigid barrels 106 amino acid residues in length

## Actin

- G-actin (G for globular), a single chain of $\sim 375$ amino acids; mass $\sim 42,000 \mathrm{D}$
- G-actin units assemble into filamentous F-actin

O = G-actin monomer

actin filament

## Intermediate filaments

- two protein chains intertwined as a helix
- pairs of helices lie side-by-side to form a linear protofilament $\sim 2-3 \mathrm{~nm}$ in diameter
- filament is a hollow bundle of 8 protofilaments, about 10 nm in diameter
- many protofilaments have lengths of the order 50 nm

## Microtubules

- heterodimer of tubulin ( $\alpha$-tubulin and $\beta$-tubulin) about 8 nm in length
- dimers assemble $\alpha$ to $\beta$ successively into a hollow microtubule consisting of 13 linear protofilaments (in almost all cells)

Measurements of persistence length
(mass per unit length $\lambda_{\mathrm{p}}$ and persistence length $\xi_{\mathrm{p}}$ )

| Polymer | Configuration | $\lambda_{\mathrm{p}}(\mathrm{D} / \mathrm{nm})$ | $\xi_{\mathrm{p}}(\mathrm{nm})$ |
| :--- | :--- | :---: | :---: |
|  |  |  |  |
| Long alkanes | linear polymer | $\sim 110$ | $\sim 0.5$ |
| Spectrin | 2-strand filament | 4,500 | $10-20$ |
| DNA | double helix | 1,900 | $53 \pm 2$ |
| F-actin | filament | 16,000 | $10-20 \times 10^{3}$ |
| Intermediate filaments | 32 strand filament | $\sim 35,000$ | $0.1-1 \times 10^{3}$ |
| Tobacco mosaic virus |  | $\sim 140,000$ | $\sim 1 \times 10^{6}$ |
| Microtubules | 13 protofilaments | 160,000 | $1-6 \times 10^{6}$ |
|  |  |  |  |

## Analysis:

- persistence length $\xi_{\mathrm{p}}=\beta \kappa_{\mathrm{f}}=\kappa_{\mathrm{f}} / k_{\mathrm{B}} T$
- $\kappa_{\mathrm{f}}=Y$ q
where $Y=$ Young's modulus, units of [energy • length ${ }^{-3}$ ]
$\mathcal{I}=$ the moment of inertia of the cross section, units of [length ${ }^{4}$ ]
- calculate $\mathcal{I}$ of a uniform solid cylinder:

$$
\mathcal{I}_{y}=\int_{-R}^{R} x^{2} \mathrm{~d} A=4 \int_{0}^{R} x^{2}\left(R^{R}-x^{2}\right)^{1 / 2} \mathrm{~d} x
$$

Integrating: $\mathcal{I}=4 R^{4} \int(x / R)^{2}\left[1-(x / R)^{2}\right]^{1 / 2} \mathrm{~d}(x / R)$
$=4 R^{4} \int \cos ^{2} \theta\left[1-\cos ^{2} \theta\right]^{1 / 2} \mathrm{~d} \cos \theta \quad$ where $x / R=\cos \theta$

$$
=4 R^{4} \int \cos ^{2} \theta \sin ^{2} \theta d \theta \quad \text { where } 0 \leq \theta \leq \pi / 2
$$

In detail: $\int \cos ^{2} \theta \sin ^{2} \theta d \theta=\int(\sin 2 \theta / 2)^{2} \mathrm{~d} \theta$

$$
\begin{align*}
& =(1 / 8) \int \sin ^{2} \alpha \mathrm{~d} \alpha \quad \text { where } 0 \leq \alpha \leq \pi \\
& =\pi / 16 \tag{3}
\end{align*}
$$

Thus: $\quad \mathcal{I}=\pi R^{4} / 4 \quad$ (solid cylinder)

- for a hollow core of radius $R_{\mathrm{i}}$, (3) is reduced by $\mathcal{I}=\pi R_{\mathrm{i}}^{4} / 4$ of the core:

$$
\begin{equation*}
\mathcal{I}_{y}=\pi\left(R^{4}-R_{\mathrm{i}}^{4}\right) / 4 \quad \text { (hollow cylinder) } \tag{4}
\end{equation*}
$$

## $\xi_{\mathrm{p}}$ and Young's modulus

- view the polymers as flexible rods; according to (1) and (2), $\xi_{\mathrm{p}}$ is

$$
\begin{equation*}
\xi_{\mathrm{p}}=Y \mathrm{I} / k_{\mathrm{B}} T \tag{5}
\end{equation*}
$$

- moment of inertia of the cross section for hollow rods of inner radius $R_{\mathrm{i}}$ and outer radius $R$ is from (4)

$$
\mathfrak{T}=\pi\left(R^{4}-R_{\mathrm{i}}^{4}\right) / 4 .
$$

- assume $R \gg R_{i}$ :

$$
\begin{equation*}
\xi_{\mathrm{p}} \cong \pi Y R^{4} / 4 k_{\mathrm{B}} T, \tag{6}
\end{equation*}
$$

good for tobacco mosaic virus $\left(R / R_{\mathrm{i}} \sim 4.5\right)$
factor-of-two error for microtubules ( $R \sim 14 \mathrm{~nm}$ and $R_{\mathrm{i}} \sim 11.5 \mathrm{~nm}$ )

- replace $R$ by the mass per unit length $\lambda_{\mathrm{p}}$ using $\lambda_{\mathrm{p}}=\rho_{\mathrm{m}} \pi R^{2}$ for a cylinder, where $\rho_{\mathrm{m}}$ is the mass per unit volume:

$$
\begin{equation*}
\xi_{\mathrm{p}} \cong\left(Y / 4 \pi k_{\mathrm{B}} T \rho_{\mathrm{m}}^{2}\right) \lambda_{\mathrm{p}}^{2} \tag{7}
\end{equation*}
$$

- compared to filament radii, $Y$ and $\rho_{\mathrm{m}}$ are relatively constant among filaments
- straight line through data is $\xi_{p}=2.5 \times 10^{-5} \lambda_{p}^{2}$, where $\xi_{p}$ is in $n m$ and $\lambda_{p}$ is in $D / n m$
- equating the fitted numerical factor
$2.5 \times 10^{-5} \mathrm{~nm}^{3} / \mathrm{D}^{2}=Y / 4 \pi k_{\mathrm{B}} T \rho_{\mathrm{m}}{ }^{2}$
$--->Y=0.5 \times 10^{9} \mathrm{~J} / \mathrm{m}^{3}$ for $k_{\mathrm{B}} T=4 \times 10^{-21} \mathrm{~J}$ and $\rho_{\mathrm{m}}=10^{3} \mathrm{~kg} / \mathrm{m}^{3}$

Some comparative values:

| material | $Y\left(\mathrm{~J} / \mathrm{m}^{3}\right)$ |
| :--- | :--- |
| diamond | $1.2 \times 10^{12}$ |
| steel | $2 \times 10^{11}$ |
| dry cellulose | $8 \times 10^{10}$ |
| bone (tension) | $1.6 \times 10^{10}$ |
| wood (along grain) | $1.4 \times 10^{10}$ |
| collagen | $1-2 \times 10^{9}$ |
| rubber | $7 \times 10^{6}$ |
